

INSTREAM USE

Hydroelectric Power

3,160,000 million gallons per day

Water used for hydroelectric power generation in 1995 was an estimated 3,160,000 Mgal/d, or 4 percent less than during 1990. (See tables 27, 28.) This total is 2.6 times the average annual runoff in the conterminous United States. (Graczyk and others, 1986). It is possible for the hydroelectric power water use to exceed average annual runoff because some water is used several times as it passes through several hydroelectric dams on a river.

Water used for hydroelectric power generation is classified as an instream use and refers to the water used in the generation of electricity at plants where the turbine generators are driven by falling water. Estimates of water used for hydroelectric power generation may vary because of the way individual estimates are made of the quantities of water passed through the plants. If the water is passed through the plants only one time, then accurate estimates of water use can be obtained by streamflow measurements and gate openings. However, it is difficult to define and obtain net water use at pumped-storage hydroelectric plants because the same water is recycled a number of times. Pumped-storage plants usually generate electric energy during peak-load periods by using water previously pumped into an elevated storage reservoir during off-peak periods when excess generating capacity is available to do so. When additional generating capacity is needed, the water can be released from the pumped-storage reservoir through a conduit to turbine generators located in a power plant at a lower level.

State agencies were asked in 1995 for the first time to report offstream hydroelectric power generation. Offstream hydroelectric power generation water use was reported for ten states and totaled 90,000 Mgal/d. California reported the most water use (69,000 Mgal/d), followed by

Maine (6,290 Mgal/d), Oregon (5,880 Mgal/d) and Pennsylvania (5,260 Mgal/d). The reported off-stream uses were included in the instream uses to be consistent with previous reports in this series.

Estimates of hydroelectric power water use and power generation, as with the thermoelectric power category, are based on more information and fewer extrapolations than for the other water-use categories. Most of the information is obtained from hydroelectric utility companies. If information is not available from utilities, then records of the power generated are obtained from the U.S. Department of Energy's Energy Information Administration (1996). The power-generation data are multiplied by water-use coefficients to obtain estimates of hydroelectric power water use. In this report, it is assumed that none of the water used for hydroelectric power generation is consumptively used. Although the quantity of water evaporated in the actual generation of hydroelectric power (consumptive use) is small, considerable depletion of the available water supply for hydroelectric power generation occurs as an indirect result of evaporation from reservoirs and repeated reuse of water within a pumped-storage power facility.

Fresh surface water provides virtually all water for hydroelectric power generation. The Pacific Northwest water-resources region had by far the largest use of water for hydroelectric power generation during 1995, more than triple the use in the Great Lakes region (figure 29), and accounts for about 40 percent of the water use for hydroelectric power generation in the Nation. Almost one-half of the water use for hydroelectric power generation in the United States occurs in Washington; Oregon, primarily on the Columbia River system; and New York (figure 30), on the Niagara and the St. Lawrence River systems.
