

# **OPENING PRESENTATION**

**LISST-TECHNOLOGY AND  
PERFORMANCE - CHALLENGES AND  
SOLUTIONS**

**-TEAM SEQUOIA**

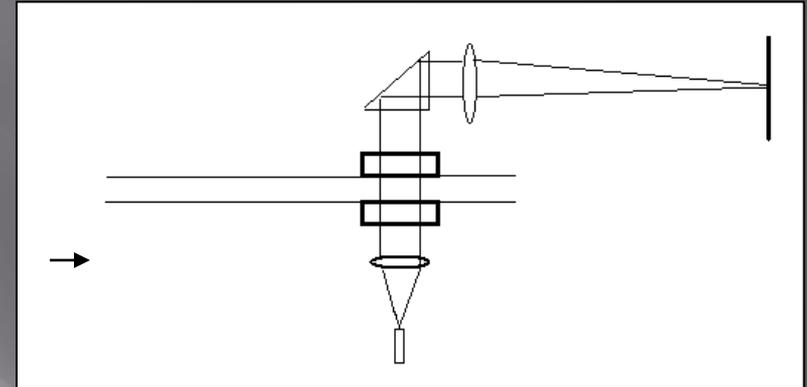

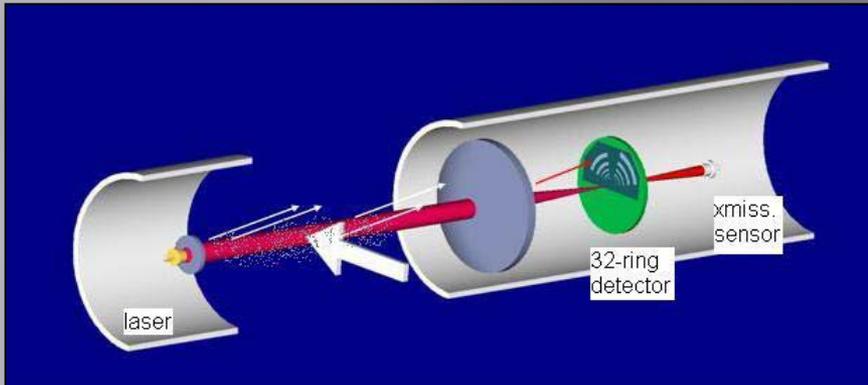

# Scope of Opening Presentation

- ❑ Technology basics – review
- ❑ Limitations of LD Technology in general
- ❑ Limitations of LISST instruments
- ❑ What can go wrong in data/operations
- ❑ What can go wrong in interpretation
- ❑ Analysis of your experiences –
  - Tim Straub; Mark Landers

# TECHNOLOGY BASICS

# LD Technology Basics

- All LD technology provides PSD and Concentration of an ensemble of particles
  - 'A view in a flash'
- LISST and all other LD instruments are NOT particle counters, and NOT samplers.

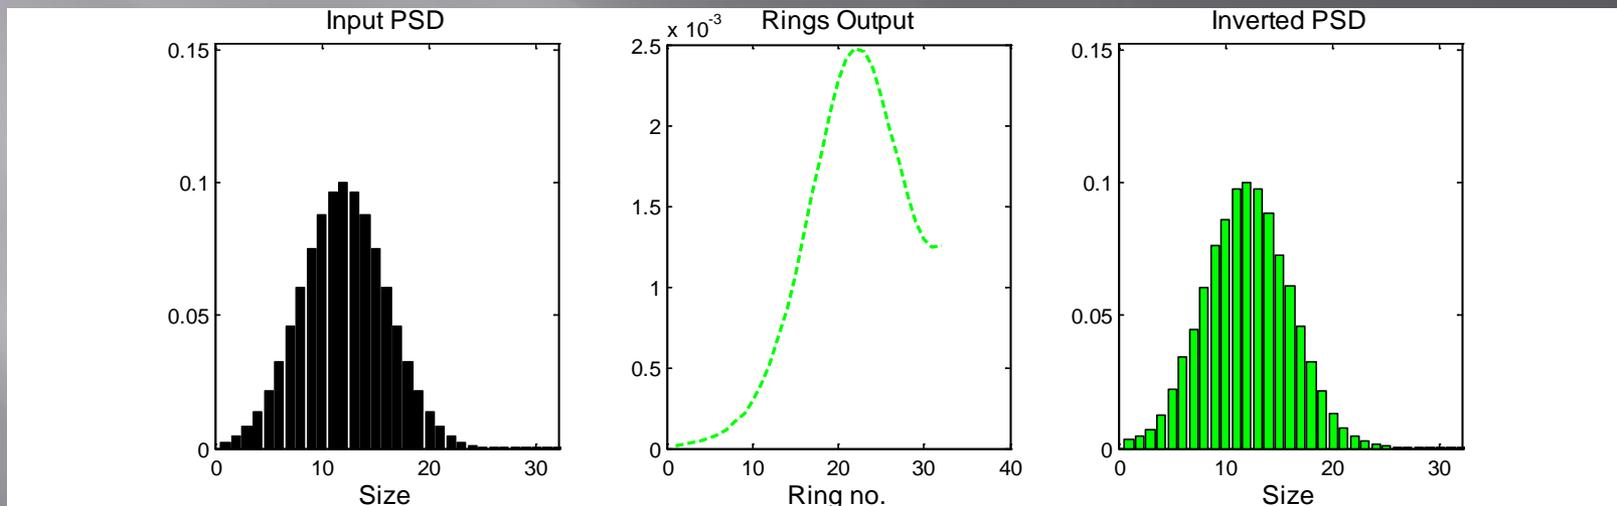

# ISO 13320:2009

ISO 13320:2009(E)

Contents	Page
Foreword .....	iv
Introduction .....	v
1 Scope .....	1
2 Normative references .....	1
3 Terms, definitions, abbreviations and symbols .....	1
3.1 Terms and definitions .....	1
3.2 Symbols .....	5
4 Principle .....	6
5 Laser diffraction instrument .....	6
6 Operational procedures .....	10
6.1 Requirements .....	10
6.2 Sample inspection, preparation, dispersion and concentration .....	10
6.3 Measurement .....	12
6.4 Precision .....	14
6.5 Accuracy .....	15
6.6 Error sources and diagnosis .....	17
6.7 Resolution and sensitivity .....	19
7 Reporting of results .....	20
Annex A (informative) Theoretical background of laser diffraction .....	22
Annex B (informative) Recommendations for instrument specifications .....	39
Annex C (informative) Dispersion liquids for the laser diffraction method .....	42
Annex D (informative) Refractive index, $n_m$ , for various liquids and solids .....	43
Annex E (informative) Recommendations to reach optimum precision in test methods .....	48
Bibliography .....	50

- ISO-13320 was written only for PSD
- Summing PSD gives concentration over the size range

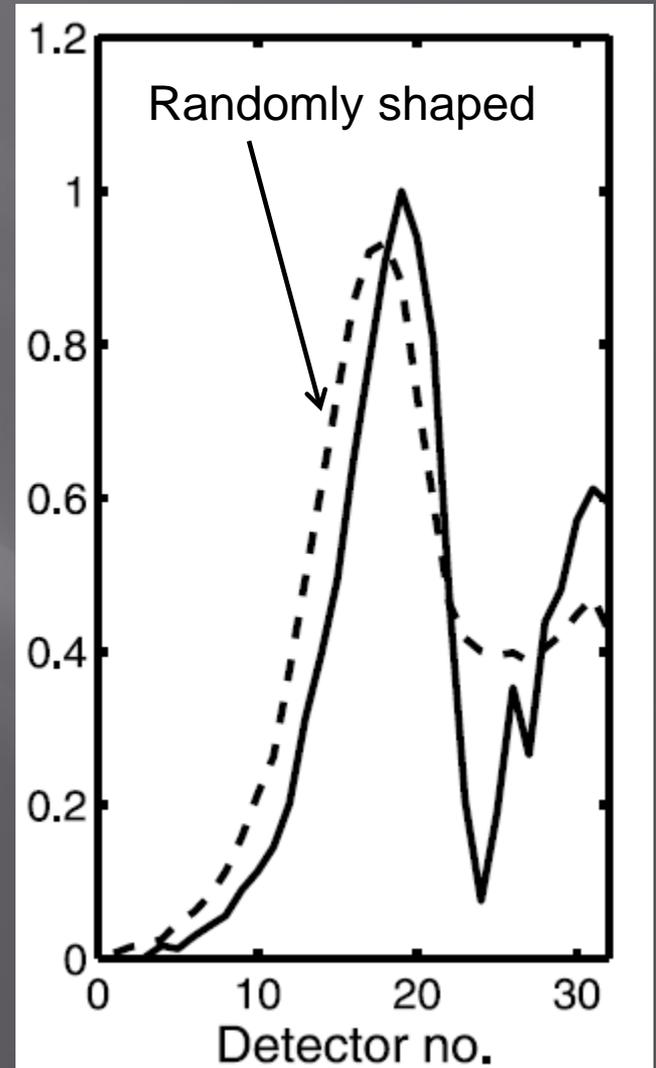

# How Laser Diffraction Works

- ▣ Particles of ANY size produce light on ALL rings
  - Light on a particular ring does NOT represent concentration of any particular size particle.
  - Common misunderstanding

# Randomly Shaped Particles

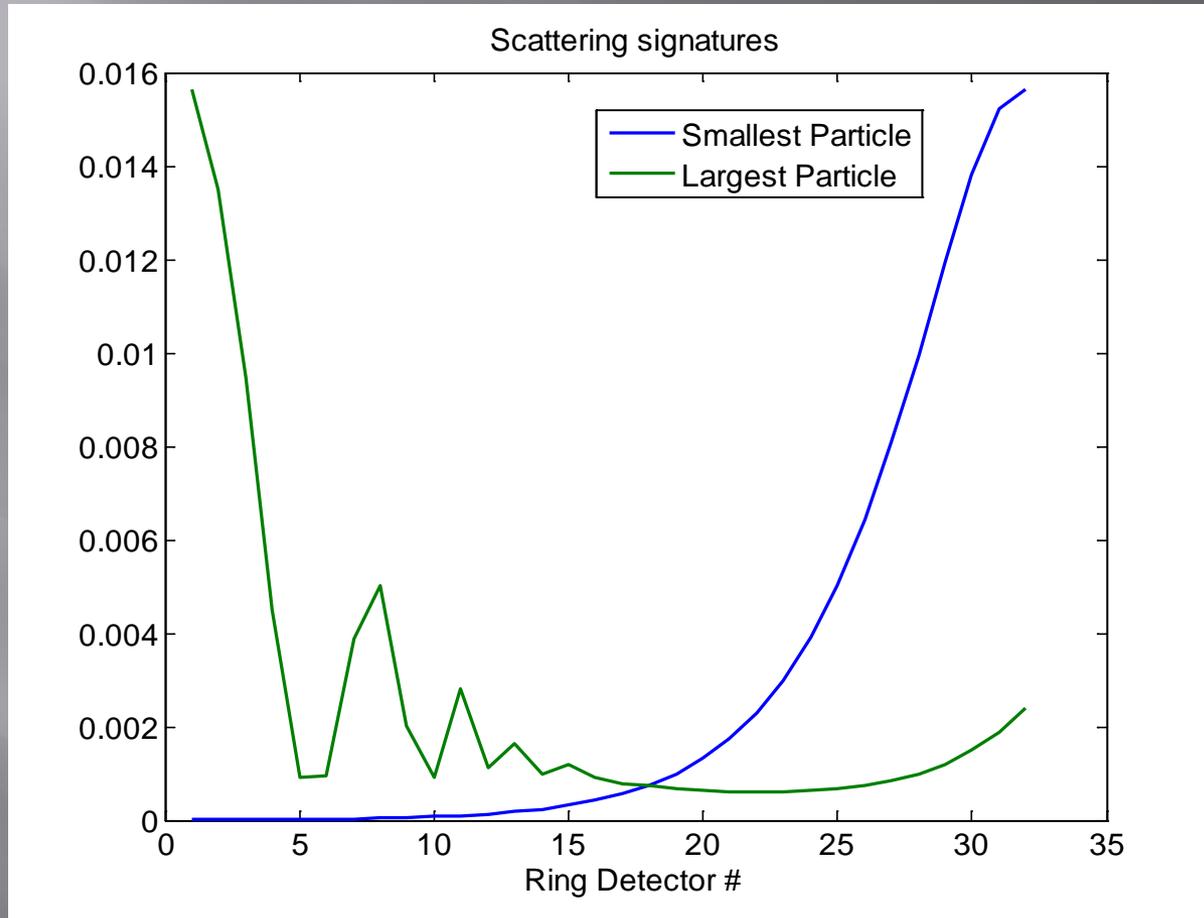

- Scattering from randomly shaped grains differ slightly from same-size spheres; this changes the size scale
- All pre-Sequoia work produced PSD of equivalent spheres
  - Only Sequoia offers inversion to give PSD of 'sieved sizes'.
- Using the randomly shaped matrices enables comparison with existing, historical SIEVE data sets

# LIMITATIONS OF LD TECHNOLOGY IN GENERAL

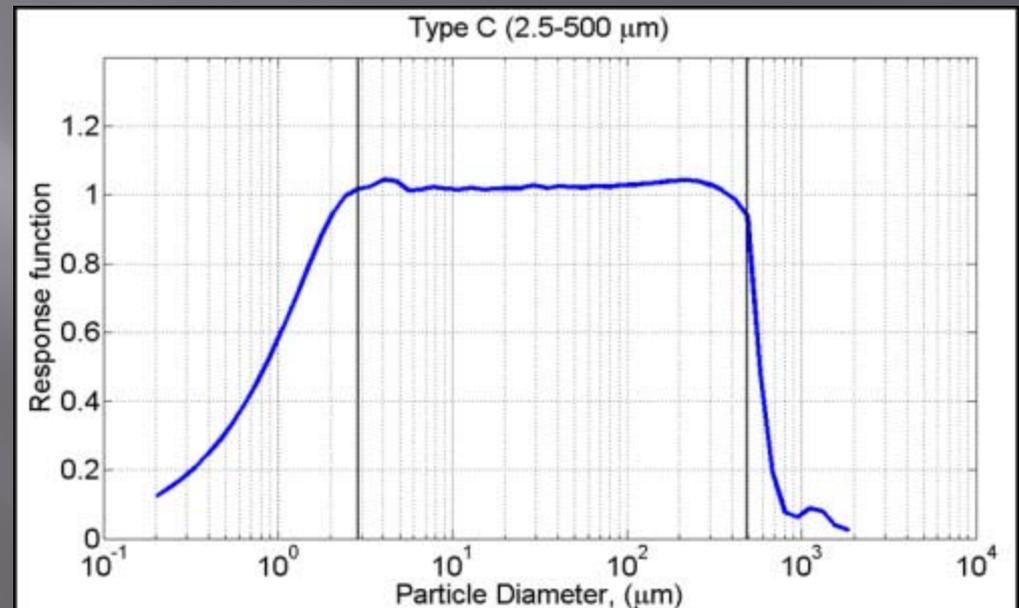

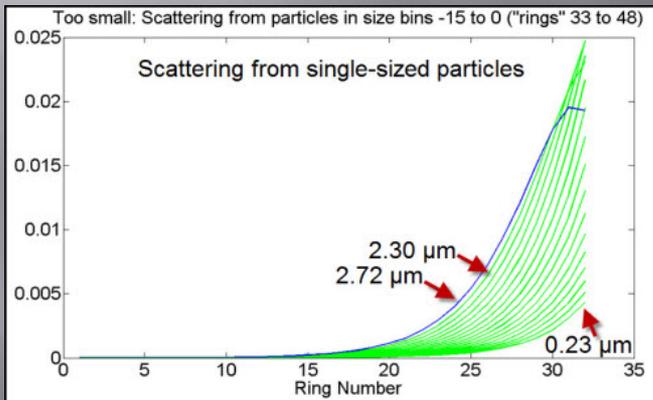

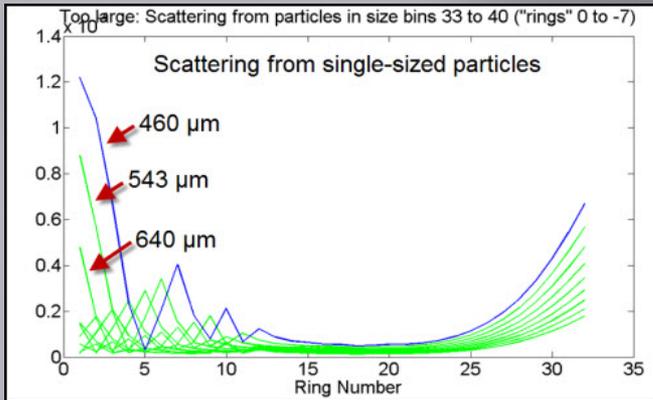

- Upper and lower size limits
- Cannot discriminate types of particles

# Upper and Lower Size Limits

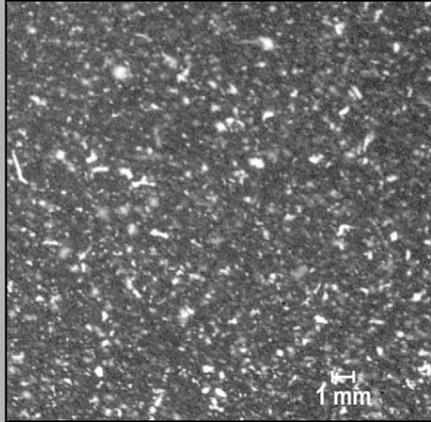

- Upper size limit derives from smallest ring
- Lower size limit derives from largest ring

# How LD sees particles outside this range

- ▣ Particles Leak into the nearest size bins
- ▣ This often produces rising tails in PSD
  - More so for particles smaller than the smallest size bin of the LISST

# Almost everything scatters

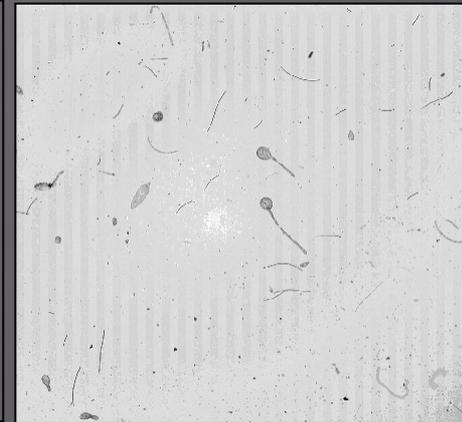

**Sediment flocs in  
the Po River, Italy**

**Schlieren /  
Scintillation**

**Bubbles**

**Phyto- and zoo-  
plankton**

- ▣ Particles, bubbles, algae, etc. but also density fluctuations caused by temperature variance
- ▣ Density-related scattering ('scintillation') invents large particles.
  - Scintillation is avoided by letting water and LISST reach identical temperature. This is common to all LD systems.

# Converting volume to mass

- ▣ All LD systems measure volume distribution
- ▣ Converting to mass requires the user to ASSUME an effective mass density and then apply that
- ▣ Easier in the lab, where all particles can be dispersed (ISO 13320:2009).
- ▣ Not easy with field data where aggregates, bubbles, low-density biological particles can be present

# LIMITATIONS OF LISST INSTRUMENTS

- ▣ Concentration limits
  - Limits exists in the field
  - Optimum accuracy at optical transmission between 0.3 and 0.98
  - For -SL: upper limit (mg/l) =  $300 \cdot d[\mu\text{m}]$
  - For -SS:  $200 \cdot d[\mu\text{m}]$
  - Lower limit limited by signal-to-noise ratio
- ▣ Size range may not cover all particles in suspension
- ▣ Clogging of intakes for pumped instruments
  - LISST-StreamSide
  - LISST-SL
- ▣ Velocity limits for isokinetic sampling and general operation (-SL only)

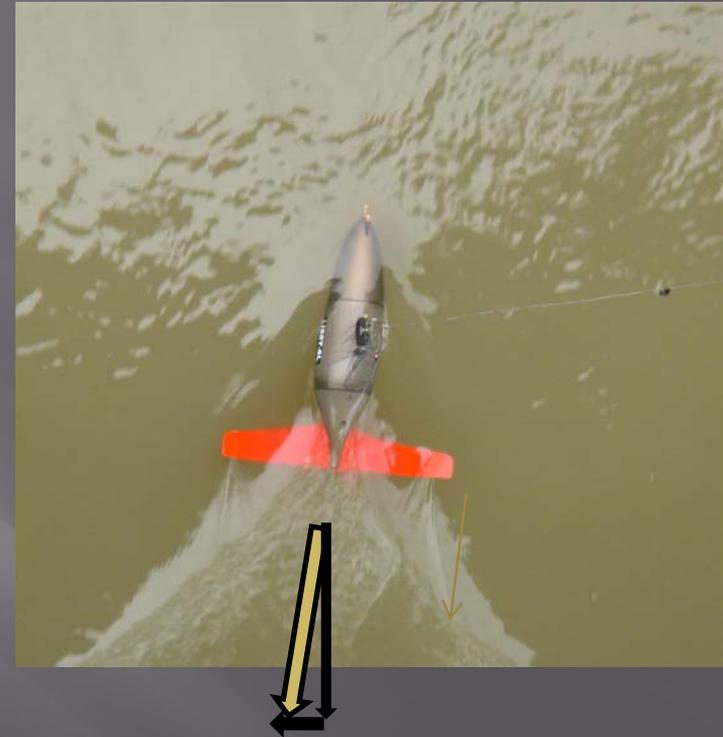

# WHAT CAN GO WRONG WHEN COLLECTING DATA

- ▣ Misalignment of optics
  - Low zscat laser power, increased zscat scattering on inner rings constant in time
- ▣ Dirty windows
  - Increased zscat scattering on middle rings
- ▣ Poor temperature equilibrium - scintillation
  - Increased scattering on inner rings, decreasing in time
- ▣ Clogging of intake by debris
- ▣ Clogging of pitot tube by debris (-SL only)

- ▣ LISST-SL pump not locked in, still adjusting during sampling
  - Lock-in ~ 2 minutes after immersion when powered
  - After lock-in isokinetic control is better than 10% as set at factory
  - Minimum river velocity for isokinetic operation is 0.5 m/s [1.65 ft/s]
- ▣ Purging of bleed port not adequate
  - Erratic velocity readings on TCB

# Is swimming a problem?

- ▣ Eddies change instantaneous flow direction
- ▣ The component of drag normal to river flow produces side-ways drift of -SL
- ▣ Because USGS samplers weight  $\gg$  drag, they are pushed less in sideways direction
- ▣ A look at video of -SL always shows wake of 'sail' aligned with flow.
- ▣ Even so, for operation in higher velocity rivers, extra weight will be needed.
  - Sequoia to design.

# WHAT CAN GO WRONG WHEN INTERPRETING DATA

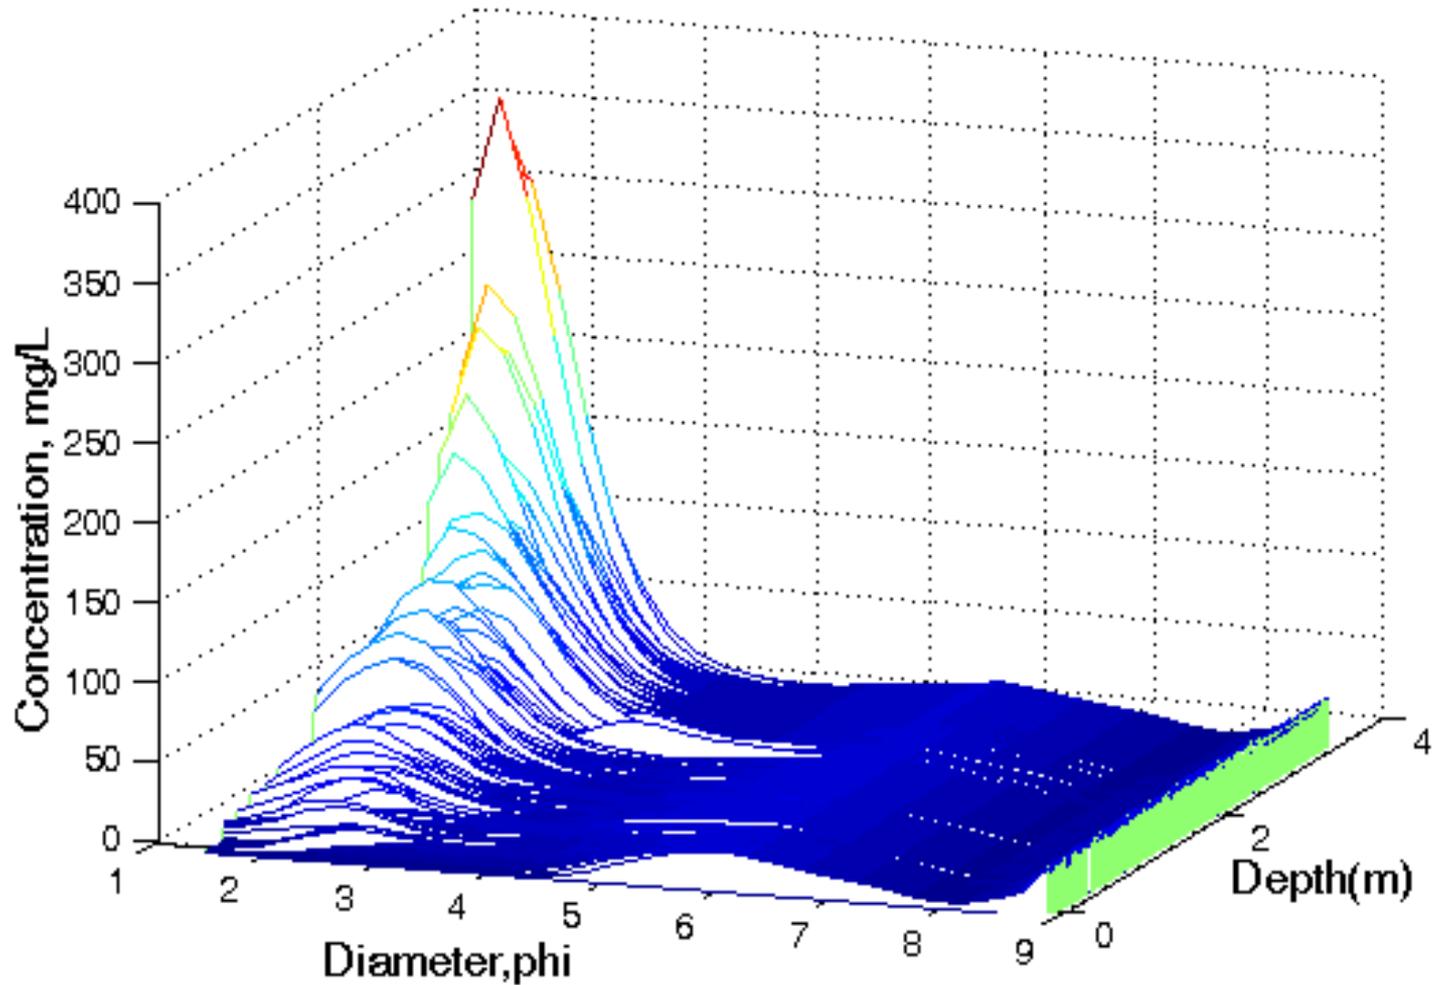

- ▣ Short LISST-SL time series is an issue
  - Makes interpretation and troubleshooting more difficult
  - Measurement duration should be  $\gg$  time-scale of local eddies
- ▣ Presence of loosely aggregated particles
  - Density  $\ll 2.65$
  - Affects conversion from volume to mass!
- ▣ Particles outside the size range
  - Will influence computation of size parameters (mean, median etc.)
  - Will overestimate total concentration

# A common source of error – Mixing

- Concentration gradients exist everywhere, in the field and lab
  - [Rouse (1937) showed  $C \sim z^{-ku^*/w_f}$ ]
- To avoid, turbulent velocity fluctuations  $\gg$  settling velocity
- Location of intake pump in a gauging station will affect measured PSD [see Cowlitz/Puyallup river data]
- Even in the lab, concentration gradients make calibrations and comparisons very difficult.

# Incomplete mixing in a river

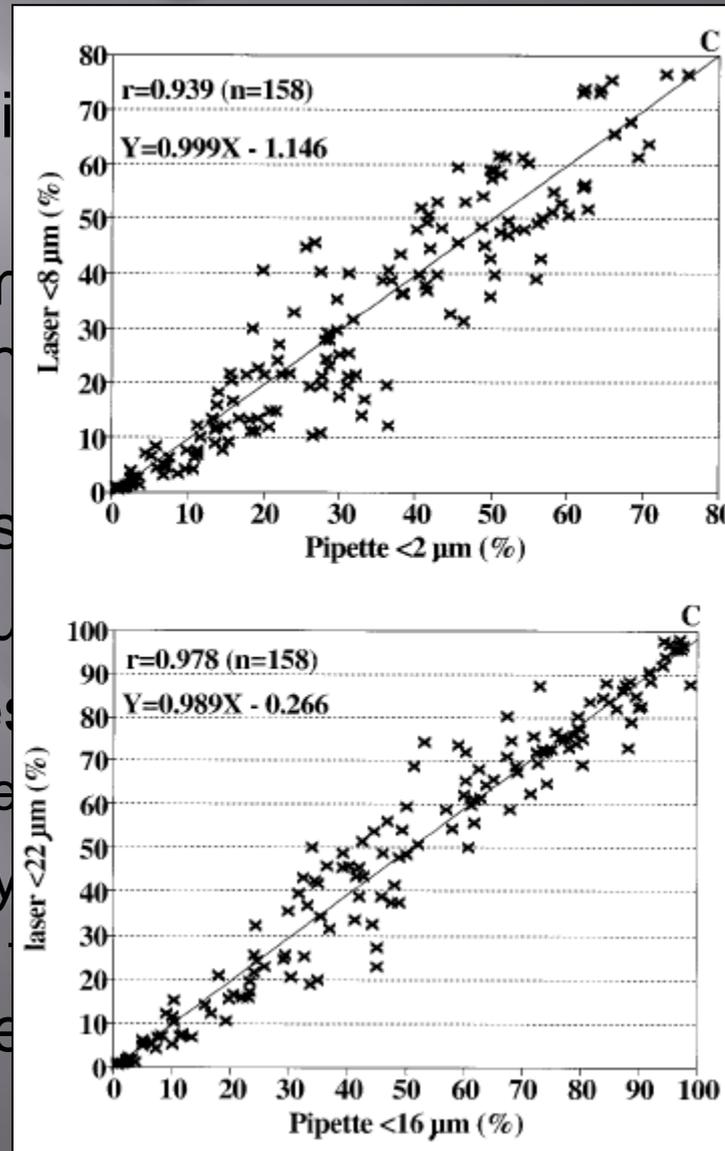

Vertical variation of size distribution seen in Cowlitz (also Puyallup) river

**YOUR EXPERIENCES**

# Comparing size distributions

- Size distribution compared.
- The pipette method is more accurate than LD for the smaller diameters (Vandenberghe 1997)
- Same applies to LD PSD should be used only for larger diameters (spheres) because discrepancies are larger than expected (size distribution differences > expected)
- Sample analysis compared to aggregation effects (in-situ)

s CANNOT be compared

the smaller diameters (Vandenberghe 1997)

LD only for larger diameters (spheres)

differences > expected

size distribution differences (in-situ)

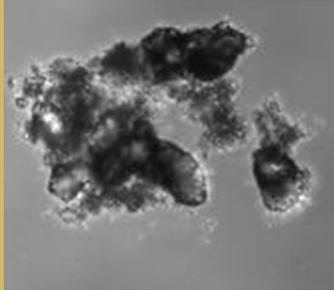

# Converting to mass

- ▣ Mass density of in-situ particles is not the same as the density of the same particles in the lab when disaggregated
- ▣ Calculating an effective in-situ density using water samples is an effective method for converting in-situ volume to mass

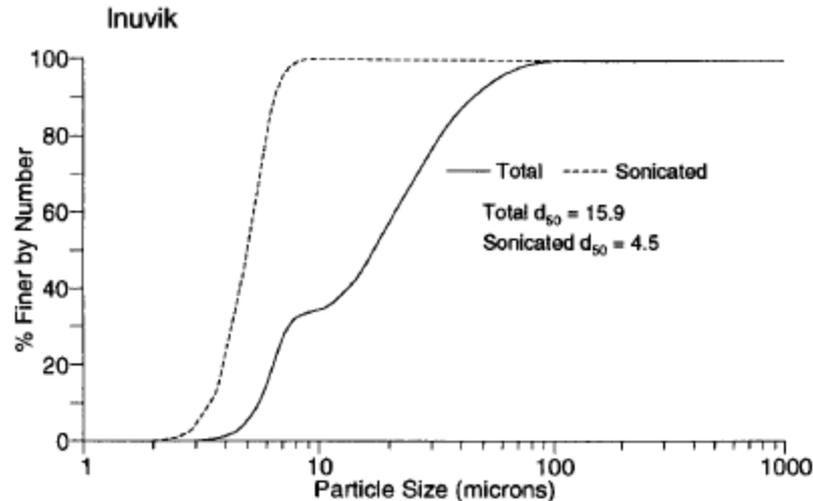

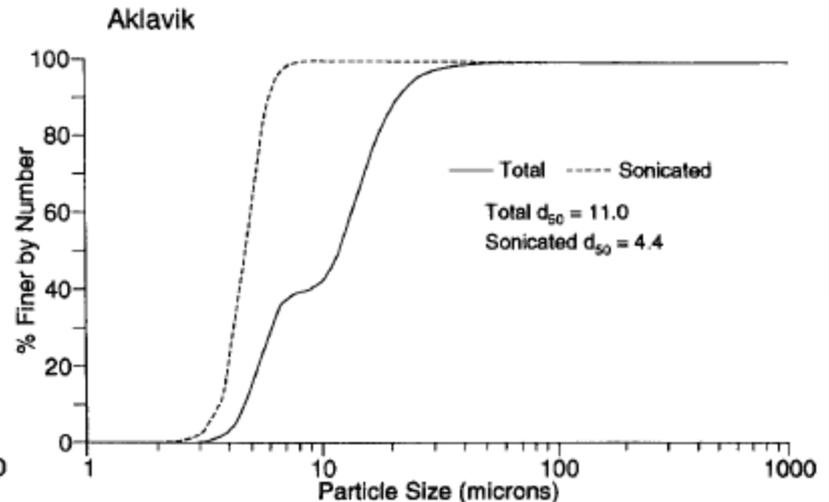

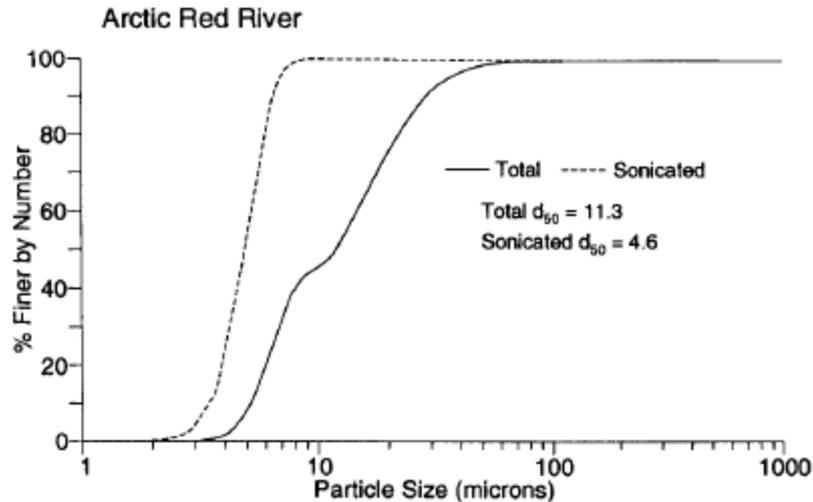

# Effective Density: Definition

- ▣ Effective Density =  $\frac{\text{Actual Mass Concentration}}{(\text{LISST}) \text{ Volume Concentration}}$
- ▣ It is NOT the density of the individual particles
- ▣ It changes in time and space depending upon conditions

# Effective Density: Example

	 <p>Sediment Grains</p>	 <p>Flocculated particles</p>	 <p>Bubbles</p>
Particle Size ( $\mu\text{m}$ )	30	30	30
Volume Conc ( $\mu\text{l/l}$ )	100	100	100
Filtered and Weighed Mass Conc (mg/l)	260	40	0
<b>Effective Density</b>	<b>2.6</b>	<b>0.4</b>	<b>0</b>

# Flocculation effect on size distribution

Arctic Rivers (Droppo et al., 1998)

No single grains  $> \sim 10 \mu\text{m}$

All in situ particles  $> 10 \mu\text{m}$  were flocs

# Conclusions

LD has strengths and limitations.

Data suggest the possibility of flocs in-situ.

Remains to examine data to be presented.
