Subject: Approval of New USGS Method (O-2437-15) Determination of Pesticides and Pesticide Degradates by Direct Aqueous Injection (DAI) LC-MS/MS

The Office of Water Quality (OWQ) has approved a new filtered-water analytical method, O-2437-15, National Water Quality Laboratory (NWQL) laboratory schedule (LS) 2437, for the determination of 229 current use pesticides and pesticide degradates (see attached table 1).

The U.S. Geological Survey (USGS) developed this method to support studies of selected pesticide compounds (113 pesticides and 116 pesticide degradates) in a variety of filtered water-matrix types including groundwater, surface water, and drinking water. Field filtration of 10-milliliter samples for LS2437 is required as described in National Field Manual for the Collection of Water Quality Data (NFM), Chapter 5.2.2.B (Sandstrom and Wilde, 2014).

The pesticide compounds in the new method were considered high priority for method development and future monitoring studies in the USGS because of potential for occurrence and persistence in streams and groundwater, and toxicity to humans and aquatic organisms. The high-priority pesticide compounds included 78 new compounds not previously monitored in USGS analytical methods for determination of pesticides in water as well as many pesticide compounds determined infrequently or in small research studies. In addition, 96 pesticide compounds are included in commonly used USGS analytical methods that will be useful for long-term monitoring studies. A unique feature of the new method is the relatively large number of pesticide degradates included that provides the ability to more thoroughly study the fate of pesticides in the environment, as well as evaluate the toxicity and exposure effects.

All method analytes are determined without sample pre-concentration or isolation using direct injection of an aliquot of the filtered sample onto a liquid chromatograph-tandem mass spectrometer (LC-MS/MS). Pesticide compounds are determined in the samples in two groups, one by the MS/MS operated in positive electrospray ionization (ESI+) mode, the other in negative electrospray ionization (ESI-) mode. For each group an aliquot of the sample (100 µL) is injected onto a liquid chromatographic column (C18 phase), and the analytes are separated using binary mobile phase of formic acid/ammonium formate-methanol for ESI+ mode or acetic acid-acetonitrile for ESI- mode. A dynamic multiple reaction monitoring (MRM) method is used on the MS/MS to collect specific quantification and qualifier ions for each analyte. Analyte identification is based on agreement between known standards with respect to chromatographic retention time and the ratio of the two characteristic MRMs. The concentration of each identified component is determined using the internal standard technique.

The Techniques and Method report describes the analytical method and presents characteristics of the method validation including bias and variability in different matrices, method detection levels (MDLs), and holding-time studies. The report also describes a comparison of the new DAI LC-MS/MS analytical method with two existing NWQL analytical methods (LS2033 and LS2060) for determination of pesticides. The results provided a characterization of the performance of the new method during implementation in routine production, including bias and variability of analytes in LS2437 over a range of environmental matrices and concentrations and in comparison to LS2033 and LS2060.

The MDLs were determined in reagent water using the U.S. Environmental Protection Agency (EPA) procedure (40 CFR part 142, appendix B). The MDLs range from 1 to 103 nanograms per liter (ng/L) for 183 analytes analyzed in the ESI positive mode, and from 2 to 106 ng/L for 42 analytes analyzed in the ESI negative mode. Four analytes had MDLs between 100 and 250 ng/L. After the method is implemented into routine productions the MDLs and reporting levels will be updated to reflect long-term method performance. The stability studies in reagent water demonstrated that the majority of the pesticide compounds were stable after 14 days of storage at 4 degrees Celsius, so these were selected as the practical holding time and storage temperature for routine sample processing.

Field samples are collected using USGS protocols for organic contaminants according to procedures in the NFM, Chapter 4 (U.S. Geological Survey, 2006). Samples are filtered at the field site using small disposable 25-mm-diameter syringe-tip filters (Q762FLD) (Sandstrom and Wilde, 2014) and samples are collected and stored in 20-mL vials (PEST bottle type, Q21FLD) until analysis.

Because there is a large backlog of samples requiring data analysis for LS2437, the NWQL plans to manage new requests for LS2437 by the custom proposal process during FY 2015. Please contact labhelp ([labhelp@usgs.gov](mailto:labhelp@usgs.gov)) to request sample analysis using LS2437 for samples in FY 2015.

This method approval process follows the technical procedures specified in OWQ Technical Memorandum 04.01 and the method is described in a USGS Techniques and Methods Report:
